Understanding Absorption Liquid Chillers

What Are Absorption Liquid Chillers?

Absorption liquid chillers are refrigeration systems that utilize a heat source to drive the cooling cycle, rather than relying solely on electrical energy like conventional compression chillers. They operate based on the principles of absorption refrigeration, where a refrigerant is absorbed by a secondary fluid (absorbent) and later desorbed through the application of heat. This process results in the transfer of heat away from the building or process, providing cooling.

Key Components of Absorption Liquid Chillers

- Generator (Desorber): Uses heat to separate the refrigerant from the absorbent.
- Condenser: Cools and condenses the refrigerant vapor into a liquid.
- Evaporator: Absorbs heat from the target environment, causing the refrigerant to evaporate.
- Absorber: Recombines refrigerant vapor with the absorbent, completing the cycle.
- Solution Pump: Circulates the absorbent-refrigerant solution between the generator and absorber.
- Heat Source: Typically waste heat, natural gas, or other thermal sources.

How Do Absorption Liquid Chillers Work?

The Refrigeration Cycle Explained

The absorption refrigeration cycle relies on the absorption and desorption processes:

- **Generation of Refrigerant Vapor:** Heat supplied to the generator causes the refrigerant (commonly water or ammonia) to vaporize from the absorbent solution.
- **Condensation:** The refrigerant vapor passes through the condenser, releasing heat to the environment and condensing into a high-pressure liquid.
- **Evaporation:** The high-pressure liquid refrigerant flows into the evaporator, absorbing heat from the space or process needing cooling, and evaporates to produce a cooling effect.
- **Absorption:** The refrigerant vapor is absorbed back into the absorbent solution in the absorber, completing the cycle.
- **Solution Pump Circulation:** The absorbent-refrigerant solution is pumped back to the generator, where the cycle repeats.

This cycle distinguishes absorption chillers from compression systems by utilizing thermal energy rather than electrical energy to operate.

Advantages of Johnson Controls Absorption Liquid Chillers

Understanding Absorption Liquid Chillers

What Are Absorption Liquid Chillers?

Absorption liquid chillers are a type of cooling system that utilizes a thermally driven process to generate chilled water, which is then used for air conditioning and process cooling. Unlike conventional vapor compression chillers that rely on electric compressors, absorption chillers employ heat—often waste heat or renewable energy—to produce cooling.

Key Components of Absorption Liquid Chillers:

- Generator: Heats the absorbent solution to separate refrigerant vapor.
- Condenser: Cools and condenses the refrigerant vapor into a liquid.
- Evaporator: Absorbs heat from the building or process, cooling the environment.

- Absorber: Recollects refrigerant vapor into the absorbent solution.
- Solution Pump: Circulates the absorbent-refrigerant mixture through the system.

How Do They Work?

The process begins with heat input at the generator, which causes the refrigerant (commonly water or ammonia) to vaporize from the absorbent solution (such as lithium bromide). The refrigerant vapor then moves to the condenser, releasing heat and condensing into a liquid. The cooled refrigerant flows into the evaporator, where it absorbs heat from the environment, providing the cooling effect. Meanwhile, the absorbent solution, now rich in refrigerant vapor, passes through the absorber, where it reabsorbs the refrigerant, completing the cycle.

This thermally driven process allows absorption chillers to operate efficiently on heat sources like waste heat from industrial processes, cogeneration systems, or solar thermal energy, making them a versatile, sustainable cooling method.
